*Exotics Plenary Meeting*

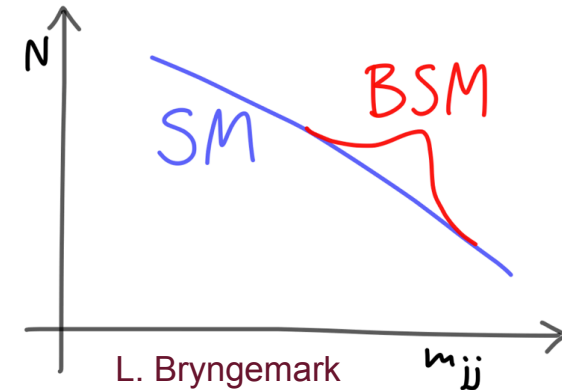

27 November 2015

- b-Tagged di-jet resonance search
- **Aiming for a paper for Moriond**
- Documentation in Place
  - [CDS Entry](#)
  - [SVN Area](#)
- Ed Board Assembled
  - A. Glazov (Chair), F. Parodi, L. Tompkins
  - First Ed Board Meet - 11th November
  - Agenda can be found [here](#)
- Plots shown today are still preliminary

- Follow similar analysis strategy to inclusive di-jet analysis.
  - **Search for resonance in invariant mass spectrum.**
  - Fit QCD background using smoothly falling function.
  - Same event selection as di-jet search.
  - This allows us to share much of the framework.
- **In addition, b-tagging is applied.**
  - Three categories - 0, 1 and 2 b-tags
- Search for generic di-jet resonance
  - Gaussian with width similar to benchmark models.
  - Two Benchmark models, which we will set limits on.
    - 1)  $Z' \Rightarrow b\bar{b}$ , double b-jet final state.
    - 2)  $b^* \Rightarrow b\gamma$ , single b-jet final state.

- Many BSM models predict heavy particles that decay into  $bb$  or  $bg$ .
  - $Z'$ ,  $b^*$ , RS Graviton...
  - b-Tagging can be used to reduce light dominated QCD background
  - Hence increased sensitivity to these models.
- Generic search performed searching for high mass resonance decaying to b-tagged jets.
  - Performed at CDF and CMS - ([CMS-PAS-EXO-12-023](#))
  - No ATLAS result from Run-1

## $Z'$ excluded at 1.7 TeV

## $b^*$ excluded at 1.5 TeV

- **Data Used**

- 25ns data with luminosity of **3.27 fb<sup>-1</sup>** (Periods D-J)
- Exclude runs with IBL Off - Due to huge drop in b-tagging performance.
- GRL: *data15\_13TeV.periodAllYear\_DetStatus-v70-pro19-04\_DQDefects-00-01-02\_PHYS\_StandardGRL\_All\_Good\_25ns.xml*

- **Trigger**

- **HLT\_j360**, lowest unprescaled single jet trigger

- **Event Selection**

- Reject events with problematic calo. reconstruction (LAr, Tile and Core Errors)
- At least two jets.
- **Leading-jet  $p_T > 440$  GeV**,      Subleading jet  $p_T > 50$  GeV
- **$m_{jj} > 1100$  GeV**, such that we are on the trigger plateau.
- **$|y^*| < 0.6$** , where  $y^* = 0.5 \cdot (y_1 - y_2)$ 
  - Central region more sensitive to BSM physics.

- **Jet Selection**

- Standard jet calibration (with JES correction applied)
- 2015 loose jet quality cuts applied.

- **MV2c20 - Fixed cut 85% efficiency working point**
  - $MV2c20 > -0.7887$
  - Calibrated and supported by flavour tagging group
  - Loose WP provides best sensitivity compared to others.
- b-jet efficiency  $\sim 50\%$  at jet- $p_T \sim 1$  TeV
- Light-jet rejection  $\sim 30$ 
  - Approximately flat, good for background modelling.
- Flat b-jet efficiency also being considered.
  - Shows promise of improving signal sensitivity of high mass resonances
  - Need to understand background modelling for this as not flat light-jet rej.

*b-jet eff. - Fixed WPs*

*light rej. - Fixed WPs*

*light rej. - Flat Eff. WPs*

- Calculate using ratio of tracks within jet cone to reconstructed calo jet.
  - Use a double ratio between b-tagged jets and inclusive jets
- Below 1% on top of JES for  $p_T < 600$  GeV
  - Then increases to  $\sim 10\%$  as  $p_T$  increases.
- Ongoing study
  - Further work required
  - Study in to if there is a component in bJES due to tracks not entering the ratio.
- Regularly presented in JES/JER Meetings

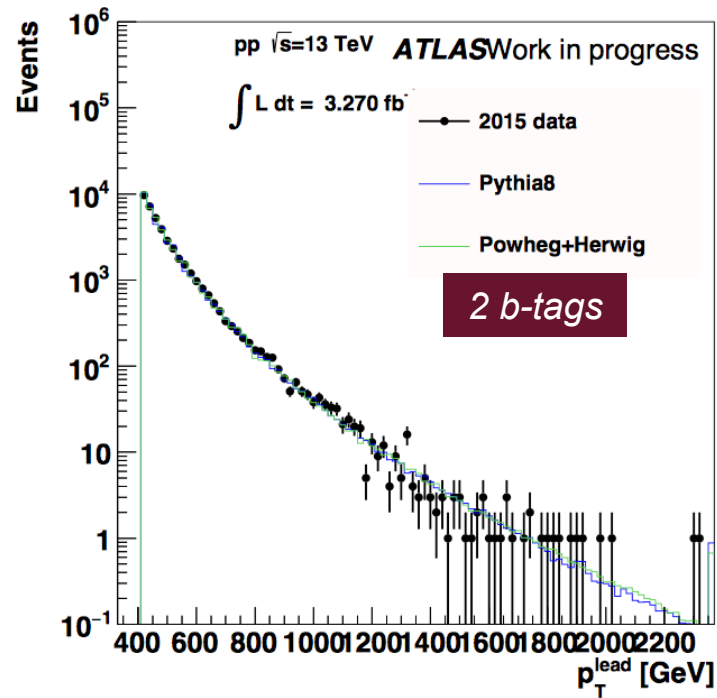

$$R' = \frac{\langle r_{bjet}^{trk} \rangle_{Data} / \langle r_{bjet}^{trk} \rangle_{MC}}{\langle r_{inc}^{trk} \rangle_{Data} / \langle r_{inc}^{trk} \rangle_{MC}}$$

where  $r^{trk} = \frac{\sum \vec{p}_T^{trk}}{p_T^{jet}}$

# 8 Data/MC Comparisons

- Compare Data to Monte Carlo
  - Pythia8 and Powheg+Herwig
- Scale factors still to be applied
  - Expect better agreement after SFs applied
- Good shape agreement with Pythia8 for...
  - Leading and Subleading Jet  $p_T$
  - $m_{jj}$  distributions
  - In both one  $b$ -tag and two  $b$ -tags

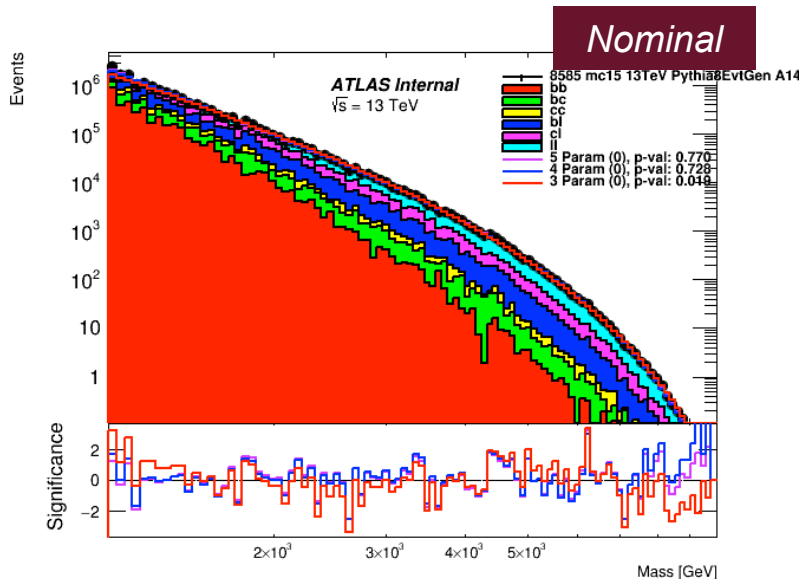

- Fit to background using smoothly falling function:

$$f(x) = p_1(1-x)^{p_2}(x)^{p_3+p_4 \ln x + p_5 \ln x^2}$$

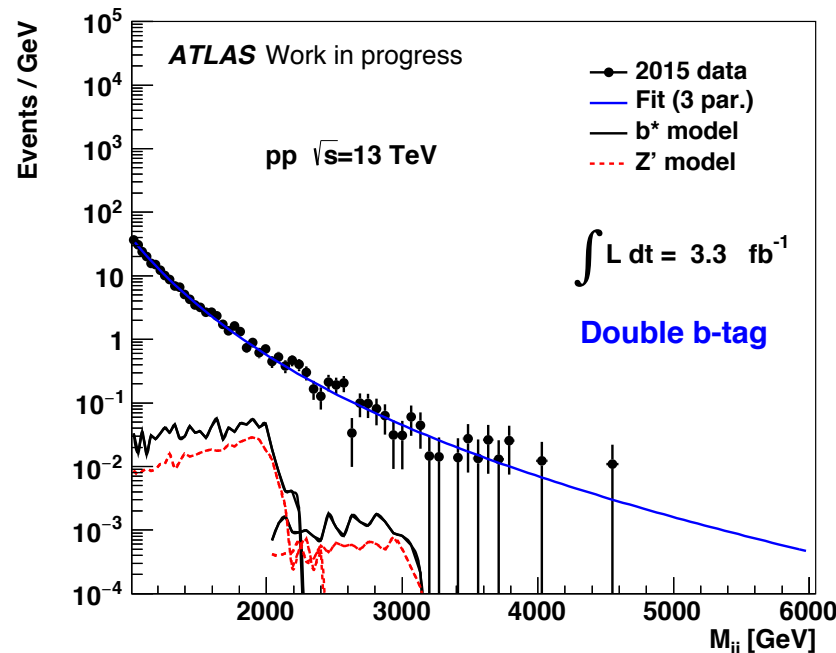

where,  $x = m_{jj}/\sqrt{s}$

- Default option is 3 parameter ( $p_4, p_5 = 0$ )
  - Use Wilks' statistic to determine if we need to change to 4-parameter fit
  - 3 Parameter sufficient to 10 fb<sup>-1</sup> with MC
- Performing cross-checks confirming that we are robust to changes in flavour fraction
  - At high mass background is dominated by lights.

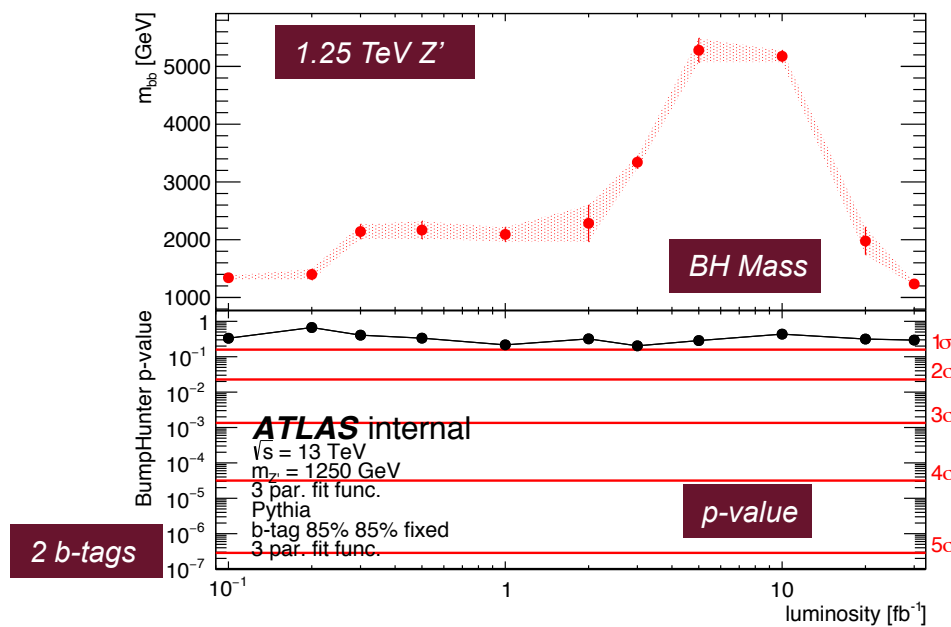

- Two benchmark models - We can set limits here.
  - **$Z' \Rightarrow b\bar{b}$**  - 1.25, 2, 3 and 4 TeV
  - **$b^* \Rightarrow b + X$**  - 1.25, 2, 3, 4 and 5 TeV
  - Templates taken from MC samples
- One cross-check channel
  - **$q^* \Rightarrow b\bar{b}$**  - 2.5, 3, 3.5 and 4.5 TeV
- Generic search performed for a Gaussian signal.
  - Resonance width taken from the benchmark

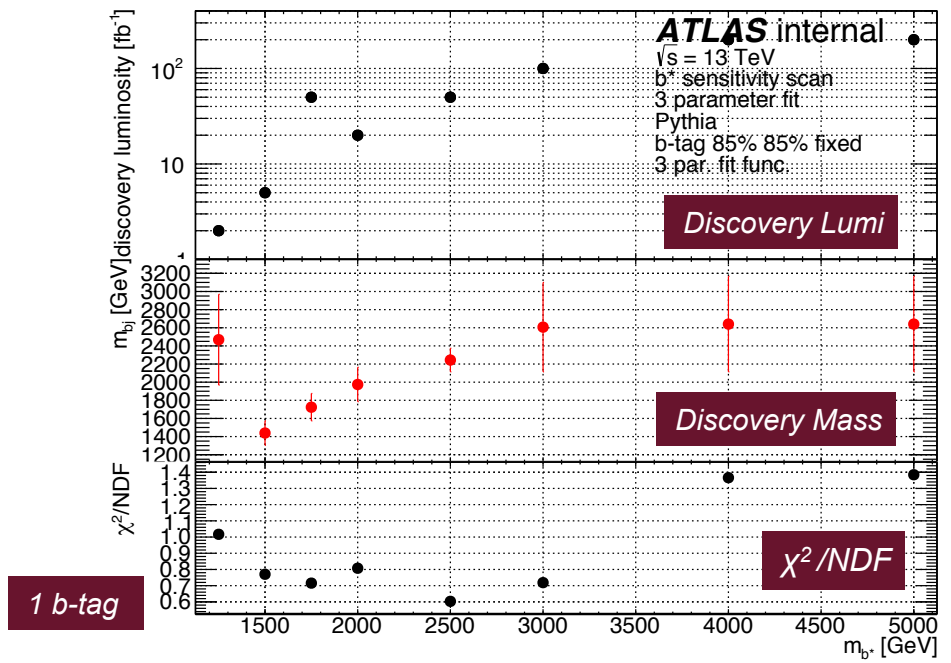

- **Low sensitivity to  $Z'$** 
  - Low cross section
  - Search for 1.25 TeV  $Z'$  slowly converging towards signal value at  $30 \text{ fb}^{-1}$
  - Also want to include  $Z' \Rightarrow cc$  and  $Z' \Rightarrow \text{light-jet}$  signals.

- **Discovery potential for  $b^*$** 
  - Larger cross-section than  $Z'$
  - Fit is stable for single b-tag
  - Sensitivity curve is not smooth
  - Under investigation

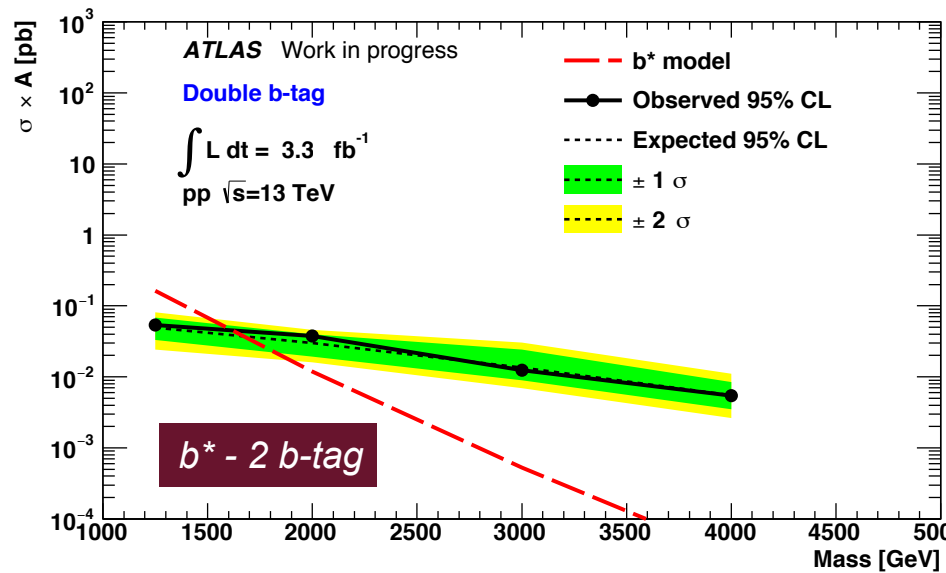

- Mass spectra in three tag categories
  - 3.27 fb<sup>-1</sup> of data, full data set.
  - Background fitted with 3 parameter function.
- Bump Hunter searches for resonances
  - Looks for a Gaussian signal
  - Searches for statistically significant deviations.
- **No deviation found more significant than 2σ**

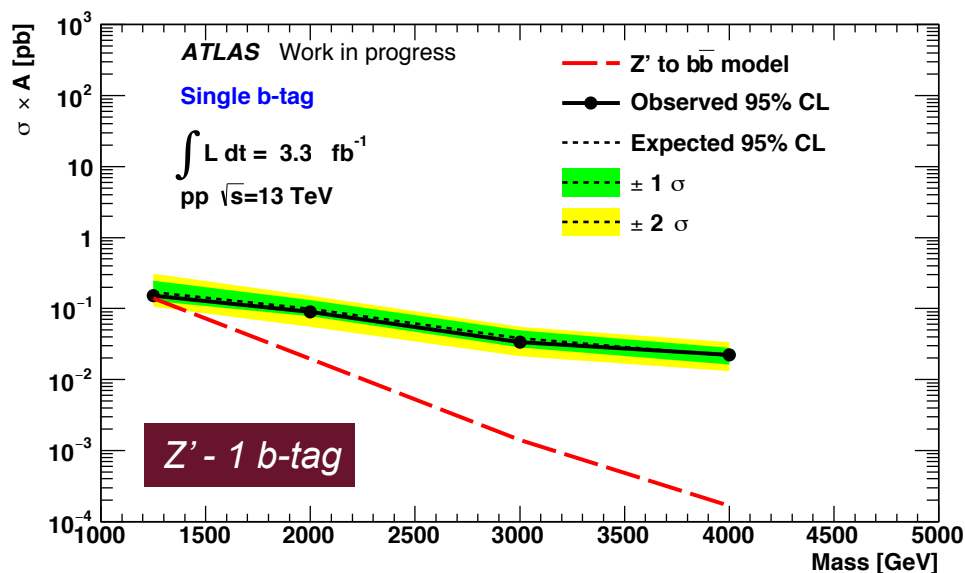

- Machinery up and running, using Di-jet statistical package
  - Deviations found by bump-hunter, test statistics by running pseudo-experiments.
  - 95% C.L. upper limiting
  - Use Bayesian approach for limit setting.
  - No Correction for acceptance.
- Systematics: Some still need to be added to the limit setting program.
  - ✓ Luminosity uncertainty - 9%
  - ✓ JES uncertainty -  $1\sigma$  up and down
  - ✓ JER uncertainty -  $1\sigma$  up and down
  - ➔ BJES uncertainty - to be added
  - ➔ B-tagged scale factor uncertainties - to be added

  - ➔ BJES uncertainty - to be added
  - ➔ B-tagged scale factor uncertainties - to be added

- b-tagged di-jet search following di-jet analysis
  - Shared cuts and framework
  - In addition applying b-tagging (1 b-tag and 2 b-tags)
- $3.27 \text{ fb}^{-1}$  of data used for this analysis.
  - Show good agreement with QCD MC
  - We find no deviations from the background fit with significance greater than  $2\sigma$ .
  - 95% C.L. upper limits set for  $b^*$  and  $Z'$ 
    - No acceptance correction
    - Some systematics need to be added
- Many studies ongoing...
  - Further sensitivity studies
  - Robustness of fit to flavour fraction
  - More systematic studies (b-tag. uncertainties)
  - BJES finalisation.
  - Inclusion of  $Z' \Rightarrow cc$  and *light*. (Ready to request)
- On course for Moriond!
  - Ed. board and documentation in place.

**UCL**

**Backup!**

- Luminosity - 9% uncertainty
- Background
  - Fit function and fit parameters
- Signal
  - JES Uncertainty
    - Branches available in analysis nTuple
    - $< 4\%$
  - JER Uncertainty
    - Assume to be negligible
  - JER Uncertainty
    - Studies performed, large for high  $p_T$  jet ( $p_T > 800$  GeV)
  - B-tagging scale factor uncertainty
- Studies to be carried out
  - Then will be added to limit setting procedure.

*BJES Uncertainty*
